Abstract

We study the Whitham equations for the Camassa-Holm equation. The equations are neither strictly hyperbolic nor genuinely nonlinear. We are interested in the initial value problem of the Whitham equations. When the initial values are given by a step function, the Whitham solution is self-similar. When the initial values are given by a smooth function, the Whitham solution exists within a cusp in the x - t plane. On the boundary of the cusp, the Whitham solution matches the Burgers solution, which exists outside the cusp.

Key words: Camassa-Holm equation, Whitham equations, Non-strictly hyperbolic, Hodograph transform

PACS: 02.30.Ik, 02.30.Jr

1 Introduction

The Camassa-Holm equation

$$u_t + (3u + 2\nu)u_x - \epsilon^2(u_{xxt} + 2u_x u_{xx} + uu_{xxx}) = 0, \quad u(x, 0; \epsilon) = u_0(x) \quad (1)$$

describes waves in shallow water when surface tension is present [2]. Here, ν is a constant parameter. The solution of the initial value problem (1) will develop singularities in a finite time if and only if some portion of the positive part of the initial “momentum” density $u_0(x) - \epsilon^2 u_0''(x) + \nu$ lies to the left of some portion of its negative part [10]. In particular, a unique global solution

Email addresses: `grava@sissa.it` (Tamara Grava), `virgilpierce@gmail.com` (V. U. Pierce), `tian@math.ohio-state.edu` (Fei-Ran Tian).

is guaranteed if $u_0(x) - \epsilon^2 u_0''(x) + \nu$ does not change its sign. These are the non-breaking initial data that we are interested in throughout this paper.

Although the zero dispersion limit of equation (1) has not been established, some of its modulation equations (i.e., Whitham equations) have been derived. The zero phase Whitham equation is

$$u_t + (3u + 2\nu)u_x = 0, \quad u(x, 0) = u_0(x), \quad (2)$$

which can be obtained from (1) by formally setting $\epsilon = 0$.

The single phase Whitham equations have been found in [1] and they can be written in the Riemann invariant form

$$u_{ix} + \lambda_i(u_1, u_2, u_3)u_{ix} = 0 \quad \text{for } -\nu < u_3 < u_2 < u_1, \quad (3)$$

where

$$\lambda_i(u_1, u_2, u_3) = u_1 + u_2 + u_3 + 2\nu - \frac{I}{\partial_{u_i} I}, \quad (4)$$

and

$$I(u_1, u_2, u_3) = \int_{u_3}^{u_2} \frac{\eta + \nu}{\sqrt{(\eta + \nu)(u_1 - \eta)(u_2 - \eta)(\eta - u_3)}} d\eta.$$

The constraint $-\nu < u_3 < u_2 < u_1$ is consistent with the non-breaking initial data mentioned in the first paragraph of this section. The integral I can be rewritten as a contour integral. Hence, it satisfies the Euler-Poisson-Darboux equations

$$2(u_i - u_j) \frac{\partial^2 I}{\partial u_i \partial u_j} = \frac{\partial I}{\partial u_i} - \frac{\partial I}{\partial u_j}, \quad i, j = 1, 2, 3 \quad (5)$$

since the integrand does so for each $\eta \neq u_i$. The Hamiltonian structure of the single phase Whitham equations for the Camassa-Holm equation was also obtained in [1] in terms of Abelian integrals. The higher phase Whitham equations can also be derived using this structure.

In this paper we will study the evolution of the Whitham solution from the zero phase to the single phase.

This problem is similar to that of the zero dispersion limit of the KdV equation [7,8,17]

$$u_t + 6uu_x + \epsilon^2 u_{xxx} = 0, \quad u(x, 0; \epsilon) = u_0(x). \quad (6)$$

It is known that the zero phase Whitham equation for the KdV equation is

$$u_t + 6uu_x = 0, \quad (7)$$

which is equivalent to (2) for the Camassa-Holm equation. The single phase Whitham equations for the KdV equation are [3,4,18]

$$u_{ix} + \mu_i(u_1, u_2, u_3)u_{ix} = 0, \quad \text{for } u_3 < u_2 < u_1, \quad (8)$$

where

$$\mu_i(u_1, u_2, u_3) = 2[u_1 + u_2 + u_3 - \frac{\tilde{I}}{\partial_{u_i} \tilde{I}}] ,$$

and

$$\tilde{I}(u_1, u_2, u_3) = \int_{u_3}^{u_2} \frac{1}{\sqrt{(u_1 - \eta)(u_2 - \eta)(\eta - u_3)}} d\eta .$$

These equations are also similar to (3) and (4) for the Camassa-Holm equation.

In the KdV case, the evolution from the zero phase to the single phase has been studied in [14]. There, the Euler-Poisson-Darboux equations (5) have played an important role. The same equations have also played a crucial role in the study of the transition from the single phase to the double phase in [5].

Although both the Camassa-Holm equation (1) and the KdV equation (6) are dispersive approximations to the Burgers equation (2) or (7), there are significant differences in the limiting dynamics. The biggest difference is that the Whitham equations (3) for the former equation are non-strictly hyperbolic (cf. (32)) while the Whitham equations (8) for the latter equation are strictly hyperbolic [9]. Non-Strictly hyperbolic Whitham equations have also been found in the higher order KdV flows [11,12,13] and the higher order defocusing NLS flows [6]. Self-similar solutions of these Whitham equations have been constructed. They are remarkably different from the self-similar solutions of the KdV-Whitham equations [11,12] or the NLS-Whitham equations [6], both of which are strictly hyperbolic.

In this paper, we will modify the method of paper [14] so that it can be used to solve the non-strictly hyperbolic Whitham equations (3) when the initial function is a smooth function. We will then study the evolution from the zero phase to the single phase for smooth initial data. When the initial function is a step-like function, we will use the method of paper [6,11,12] to study the same evolution.

The organization of the paper is as follows. In Section 2, we will introduce an initial value problem which describes the evolution of phases. We will also discuss how to use the hodograph transform to solve non-strictly hyperbolic Whitham equations. In Section 3, we will study the properties of the eigen-speeds of the single phase Whitham equations. We will study the initial value problem when the initial function $u_0(x)$ is a step-like function in Section 4 and when $u_0(x)$ is a smooth decreasing function in Section 5.

2 An Initial Value Problem

We describe the initial value problem for the Burgers equation (2) and Whitham equations (3) as follows (see Figure 1.). Consider a horizontal motion of the initial curve $u = u_0(x)$. At the beginning, the curve evolves according to the Burgers equation (2). The Burgers solution breaks down in a finite time. Immediately after the breaking, the curve develops three branches. Denote these three branches by u_1 , u_2 , and u_3 . Their motion is governed by the Whitham equations (3). As time goes on, the Whitham solution may develop singularities and more branches are created. However, our focus is on the evolution of the solution of the Whitham equations from the one branch regime to the three branch regime.

Fig. 1. Profile of the Burgers and Whitham solutions. The Burgers solution u of (2) lives in the single value regions while the Whitham solution u_1 , u_2 and u_3 of (3) reside in the multiple value region.

The Burgers solution u of (2) and the Whitham solution u_1 , u_2 , u_3 of (3) must match on the trailing edge $x = x_-(t)$ and leading edge $x = x_+(t)$. We see from Figure 1 that

$$\begin{cases} u_1 = u \\ u_2 = u_3 \end{cases} \quad (9)$$

must be imposed on the trailing edge, and that

$$\begin{cases} u_1 = u_2 \\ u_3 = u \end{cases} \quad (10)$$

must be satisfied on the leading edge.

In this paper, we consider the initial function $u_0(x)$ that is monotone. Since the Burgers solution will not develop any shock if $u_0(x)$ is an increasing function, we will focus on decreasing initial functions. Denoting the inverse function of $u_0(x)$ by $f(u)$, the Burger equation (2) can be solved using the method of characteristics; its solution is given implicitly by a hodograph transform,

$$x = (3u + 2\nu)t + f(u) . \quad (11)$$

The solution method (11) has been generalized to solve the first order quasi-linear hyperbolic equations which can be written in Riemann invariant form and which are strictly hyperbolic

$$\frac{\partial u_i}{\partial t} + s_i(u_1, \dots, u_n) \frac{\partial u_i}{\partial x} = 0 , \quad i = 1, 2, \dots, n. \quad (12)$$

The strict hyperbolicity means that the wave propagation speeds s_i 's do not coincide.

We include Tsarev's theorem for completeness [14,16].

Theorem 1 *If $w_i(u_1, u_2, \dots, u_n)$'s solve the linear equations*

$$\frac{\partial w_i}{\partial u_j} = A_{ij}(w_i - w_j) \quad (13)$$

with

$$A_{ij} = \frac{\frac{\partial s_j}{\partial u_j}}{s_i - s_j} \quad (14)$$

for $i, j = 1, 2, \dots, n$ and $i \neq j$, then the solution $(u_1(x, t), \dots, u_n(x, t))$ of the hodograph transform,

$$x = s_i(u_1, u_2, \dots, u_n)t + w_i(u_1, u_2, \dots, u_n) \quad (15)$$

satisfies equations (12). Conversely, any solution $(u_1(x, t), \dots, u_n(x, t))$ of equations (12) can be obtained in this way in the neighborhood of (x_0, t_0) at which u_{ix} are not all vanishing.

The strict hyperbolicity, i.e., $s_i \neq s_j$ for $i \neq j$, of (12) is assumed to ensure that A_{ij} 's of (14) are not singular.

The result is classical when $n = 2$.

The validity of this theorem hinges on two factors. First, the linear equations (13) must have solutions. Secondly, the hodograph transform (15) must not be degenerate, i.e., it can be solved for u_i 's as functions of x and t . One interesting observation is that the Jacobian matrix of (15) is always diagonal on the solution $(u_1(x, t), \dots, u_n(x, t))$.

Corollary 2 *At the solution $(u_1(x, t), \dots, u_n(x, t))$ of $x = s_i(u_1, u_2, \dots, u_n)t + w_i(u_1, u_2, \dots, u_n)$, $i = 1, 2, \dots, n$, the partial derivatives*

$$\frac{\partial(s_i t + w_i)}{\partial u_j} = 0$$

for $i \neq j$.

Proof.

$$\begin{aligned} \frac{\partial(s_i t + w_i)}{\partial u_j} &= \frac{\partial s_i}{\partial u_j} t + \frac{\partial w_i}{\partial u_j} \\ &= A_{ij}[(s_i t + w_i) - (s_j t + w_j)] \\ &= 0. \end{aligned}$$

□

Another aspect of Theorem 1 is that it is a local result. Solutions produced by the hodograph transform are, in general, local in nature. However, global solutions can still be obtained if the conditions of the theorem are satisfied globally [5,14].

The Whitham equations (3) will be shown to be non-strictly hyperbolic, i.e., λ_i 's coincide at some points (u_1, u_2, u_3) where $0 < u_3 + \nu < u_2 + \nu < u_1 + \nu$. However, Theorem 1 can still be applied to equations (3) since the functions A_{ij} 's of (14) are still non-singular for the Whitham equations (3), even at the points of non-strict hyperbolicity.

Lemma 3

$$B_{ij} := \frac{\frac{\partial \lambda_i}{\partial u_j}}{\lambda_i - \lambda_j} = \frac{1}{2} \frac{(\lambda_i - \gamma) - 2(u_i - u_j)}{(\lambda_j - \gamma)(u_i - u_j)}, \quad i \neq j,$$

where $\gamma = u_1 + u_2 + u_3 + 2\nu$.

Proof.

By (4), we calculate

$$\begin{aligned} \lambda_i - \lambda_j &= I \frac{\partial_{u_i} I - \partial_{u_j} I}{(\partial_{u_i} I)(\partial_{u_j} I)} = 2I \frac{(u_i - u_j) \partial_{u_i u_j}^2 I}{(\partial_{u_i} I)(\partial_{u_j} I)}, \\ \frac{\partial \lambda_i}{\partial u_j} &= \frac{2(u_i - u_j) \partial_{u_i u_j}^2 I}{\partial_{u_i} I} + \frac{I \partial_{u_i u_j}^2 I}{(\partial_{u_i} I)^2}, \end{aligned}$$

where we have used (5). Hence, we get

$$\begin{aligned}
B_{ij} &= \frac{2(u_i - u_j) + \frac{I}{\partial_{u_i} I}}{\frac{2I}{\partial_{u_j} I}(u_i - u_j)} \\
&= \frac{1}{2} \frac{(\lambda_i - \gamma) - 2(u_i - u_j)}{(\lambda_j - \gamma)(u_i - u_j)},
\end{aligned}$$

where we have used (4) to express $I/\partial_{u_i} I$. $\square$

3 The Single Phase Whitham Equations

In this section, we will summarize some of the properties of the speeds λ_i 's of (4) for later use.

Function I of (4) is a complete elliptic integral; indeed,

$$I(u_1, u_2, u_3) = \frac{2(u_3 + \nu)\Pi(\rho, s)}{\sqrt{(u_1 - u_3)(u_2 + \nu)}}, \quad (16)$$

where $\Pi(\rho, s)$ is the complete integral of third kind, and

$$\rho = \frac{u_2 - u_3}{u_2 + \nu}, \quad s = \frac{(u_2 - u_3)(u_1 + \nu)}{(u_1 - u_3)(u_2 + \nu)}. \quad (17)$$

Properties of complete elliptic integrals of the first, second and third kind are listed in Appendix A.

Using the well known derivative formulae (A.3) and (A.4), one is able to rewrite λ_i of (4) as [1]

$$\begin{aligned}
\lambda_1(u_1, u_2, u_3) &= u_1 + u_2 + u_3 + 2\nu + 2(u_1 - u_2) \frac{(u_3 + \nu)\Pi(\rho, s)}{(u_2 + \nu)E(s)}, \\
\lambda_2(u_1, u_2, u_3) &= u_1 + u_2 + u_3 + 2\nu + 2(u_3 - u_2) \frac{(1 - s)\Pi(\rho, s)}{E(s) - (1 - s)K(s)}, \\
\lambda_3(u_1, u_2, u_3) &= u_1 + u_2 + u_3 + 2\nu + 2(u_2 - u_3) \frac{(u_3 + \nu)\Pi(\rho, s)}{(u_2 + \nu)[E(s) - K(s)]}.
\end{aligned} \quad (18)$$

Here $K(s)$ and $E(s)$ are complete elliptic integrals of the first and second kind.

Using inequalities (A.9), we obtain

$$\lambda_1 - (u_1 + u_2 + u_3 + 2\nu) > 0 , \quad (19)$$

$$\lambda_2 - (u_1 + u_2 + u_3 + 2\nu) < 0 , \quad (20)$$

$$\lambda_3 - (u_1 + u_2 + u_3 + 2\nu) < 0 , \quad (21)$$

for $u_1 > u_2 > u_3 > -\nu$. In view of (A.5-A.8) and (A.10-A.11), we find that λ_1 , λ_2 and λ_3 have behavior

(1) At $u_2 = u_3$,

$$\begin{aligned} \lambda_1(u_1, u_2, u_3) &= 3u_1 + 2\nu , \\ \lambda_2(u_1, u_2, u_3) &= \lambda_3(u_1, u_2, u_3) = u_1 + 2u_3 + 2\nu - \frac{4(u_3 + \nu)(u_1 - u_3)}{u_1 + \nu} . \end{aligned} \quad (22)$$

(2) At $u_1 = u_2$,

$$\begin{aligned} \lambda_1(u_1, u_2, u_3) &= \lambda_2(u_1, u_2, u_3) = 2u_1 + u_3 + 2\nu , \\ \lambda_3(u_1, u_2, u_3) &= 3u_3 + 2\nu . \end{aligned} \quad (23)$$

Lemma 4

$$\frac{\partial \lambda_3}{\partial u_3} < \frac{3}{2} \frac{\lambda_2 - \lambda_3}{u_2 - u_3} < \frac{\partial \lambda_2}{\partial u_2}$$

for $0 < u_3 + \nu < u_2 + \nu < u_1 + \nu$.

Proof.

Comparing formulae (4) and (18), we use (16) to obtain

$$\frac{\partial I}{\partial u_2} = \frac{\sqrt{(u_1 - u_3)(u_2 + \nu)}}{(u_2 - u_3)(u_1 - u_2)} [E - (1 - s)K] . \quad (24)$$

Differentiating (4) for λ_2 and using (24) yields

$$\begin{aligned} \frac{\partial \lambda_2}{\partial u_2} &= \frac{I \partial_{u_2 u_2}^2 I}{(\partial_{u_2} I)^2} \\ &= \frac{(u_3 + \nu) \Pi}{(u_2 + \nu) [E - (1 - s)K]^2} \times \\ &\quad \times \left\{ \left[s + \frac{u_2 - u_3}{u_1 - u_3} - 2 \frac{u_1 - u_2}{u_1 - u_3} \right] [E - (1 - s)K] + s(1 - s)K \right\} . \end{aligned} \quad (25)$$

Using formulae (18) for λ_2 and λ_3 , we obtain

$$\lambda_2(u_1, u_2, u_3) - \lambda_3(u_1, u_2, u_3) = \frac{2(u_2 - u_3)(u_3 + \nu) \Pi M(u_1, u_2, u_3)}{(u_2 + \nu)(K - E)[E - (1 - s)K]} , \quad (26)$$

where

$$M(u_1, u_2, u_3) = [1 + \frac{u_1 - u_2}{u_1 - u_3}]E - [\frac{u_1 - u_2}{u_1 - u_3} + (1 - s)]K . \quad (27)$$

We then obtain from (25) and (26) that

$$\frac{\partial \lambda_2}{\partial u_2} - \frac{3}{2} \frac{\lambda_2 - \lambda_3}{u_2 - u_3} = - \frac{(u_3 + \nu)(4 - 3s)\Pi E^2}{(u_2 + \nu)[K - E][E - (1 - s)K]^2} \left\{ (1 - s)\left(\frac{K}{E}\right)^2 - 2\left(\frac{K}{E}\right) + \frac{4 + s}{4 - 3s} \right\} > 0 ,$$

where the inequality follows from the negativity of the function in the bracket (c.f. (4.18) of [14]). This proves part of the lemma. The other part can be shown in the same way.

□

We conclude this section with a few calculations. We use (A.1) and (A.2) to calculate the derivative of (27)

$$\begin{aligned} \frac{\partial M(u_1, u_2, u_3)}{\partial u_2} &= \frac{1}{2(u_1 - u_3)} \left\{ \left[2 + \frac{(u_1 + \nu)(u_3 + \nu)}{(u_2 + \nu)^2} \right] K \right. \\ &\quad \left. - \left[2 + \frac{u_1 + \nu}{u_2 + \nu} \right] E \right\} , \end{aligned} \quad (28)$$

$$\frac{\partial^2 M(u_1, u_2, u_3)}{\partial u_2^2} = \frac{(u_1 + \nu)[4(u_1 + \nu) - 2(u_2 + \nu) + (u_3 + \nu)]E}{4(u_1 - u_3)(u_1 - u_2)(u_2 + \nu)^2} . \quad (29)$$

Finally, we use the expansions (A.5-A.6) for K and E to obtain

$$\begin{aligned} M(u_1, u_2, u_3) &= \frac{\pi}{2} \left\{ \frac{(u_2 - u_3)s}{2(u_1 - u_3)} + \frac{1}{16} \left(1 - \frac{3(u_1 - u_2)}{u_1 - u_3} \right) s^2 \right. \\ &\quad \left. + \frac{3}{128} \left(1 - \frac{5(u_1 - u_2)}{u_1 - u_3} \right) s^3 + O(s^4) \right\} \\ &= \frac{\pi}{2} \left\{ \left[\frac{u_2 + \nu}{2(u_1 + \nu)} + \frac{1}{16} \left(1 - \frac{3(u_1 - u_2)}{u_1 - u_3} \right) \right] s^2 \right. \\ &\quad \left. + \frac{3}{128} \left(1 - \frac{5(u_1 - u_2)}{u_1 - u_3} \right) s^3 + O(s^4) \right\} , \end{aligned} \quad (30)$$

where we have used formula (17) for s in the last equality.

4 Step-like Initial Data

In this section, we will consider the step-like initial data

$$u_0(x) = \begin{cases} a & x < 0 \\ b & x > 0 \end{cases}, \quad a \neq b \quad (31)$$

for equation (1). Since the solution of (2) will never develop a shock when $a \leq b$, we will be interested only in the case $a > b$. We classify the initial data (31) into two types:

- (I) $a + \nu > 4(b + \nu)$,
- (II) $a + \nu \leq 4(b + \nu)$.

We will solve the initial value problem for the Whitham equations for these two types of initial data.

4.1 Type I: $a + \nu > 4(b + \nu)$

Fig. 2. Self-Similar solution of the Whitham equations for $a = 2$, $b = 0$ and $\nu = 1/20$ of type I.

Theorem 5 (see Figure 2.) For the step-like initial data $u_0(x)$ of (31) with $0 < b + \nu < (a + \nu)/4$, the solution of the Whitham equations (3) is given by

$$u_1 = a, \quad x = \lambda_2(a, u_2, u_3) t, \quad x = \lambda_3(a, u_2, u_3) t \quad (32)$$

for $(3a - \nu)/4 < x/t \leq \alpha$ and by

$$u_1 = a, \quad x = \lambda_2(a, u_2, b) t, \quad u_3 = b \quad (33)$$

for $\alpha t \leq x < (2a + b + 2\nu)t$, where $\alpha = \lambda_2(a, u^*, b)$ and u^* is the unique solution u_2 of $\lambda_2(a, u_2, b) = \lambda_3(a, u_2, b)$ in the interval $b < u_2 < a$. Outside the region $(3a - \nu)/4 < x/t < 2a + b + 2\nu$, the solution of the Burgers equation (2) is given by

$$u \equiv a \quad x/t \leq (3a - \nu)/4 \quad (34)$$

and

$$u \equiv b \quad x/t \geq 2a + b + 2\nu. \quad (35)$$

The boundaries $x/t = (3a - \nu)/4$ and $x/t = 2a + b + 2\nu$ are the trailing and leading edges, respectively, of the dispersive shock. They separate the solution into the region governed by the single phase Whitham equations and the region governed by the Burgers equation.

The proof of Theorem 5 is based on a series of lemmas.

We first show that the solutions defined by formulae (32) and (33) indeed satisfy the Whitham equations (3) [16].

Lemma 6 (i) *The functions u_1 , u_2 and u_3 determined by equations (32) give a solution of the Whitham equations (3) as long as u_2 and u_3 can be solved from (32) as functions of x and t .*
(ii) *The functions u_1 , u_2 and u_3 determined by equations (33) give a solution of the Whitham equations (3) as long as u_2 can be solved from (33) as a function of x and t .*

Proof.

(i) u_1 obviously satisfies the first equation of (3). To verify the second and third equations, we observe that

$$\frac{\partial \lambda_2}{\partial u_3} = \frac{\partial \lambda_3}{\partial u_2} = 0 \quad (36)$$

on the solution of (32). This follows from Lemma 3.

We then calculate the partial derivatives of the second equation of (32) with respect to x and t .

$$1 = \frac{\partial \lambda_2}{\partial u_2} t(u_2)_x, \quad 0 = \frac{\partial \lambda_2}{\partial u_2} t(u_2)_t + \lambda_2,$$

which give the second equation of (3).

The third equation of (3) can be verified in the same way.

(ii) The second part of Lemma 6 can easily be proved in a similar manner.

□

We now determine the trailing edge. Eliminating x and t from the last two equations of (32) yields

$$\lambda_2(a, u_2, u_3) - \lambda_3(a, u_2, u_3) = 0 . \quad (37)$$

In view of formula (26), we replace (37) by

$$\frac{M(a, u_2, u_3)}{s^2} = 0 . \quad (38)$$

Therefore, at the trailing edge where $u_2 = u_3$, i.e., $s = 0$, equation (38), in view of the expansion (30), becomes

$$\frac{u_3 + \nu}{2(a + \nu)} + \frac{1}{16} \left[1 - \frac{3(a - u_3)}{a - u_3} \right] = 0 ,$$

which gives $u_2 = u_3 = (a - 3\nu)/4$.

Lemma 7 *Equation (38) has a unique solution satisfying $u_2 = u_3$. The solution is $u_2 = u_3 = (a - 3\nu)/4$. The rest of equations (32) at the trailing edge are $u_1 = a$ and $x/t = \lambda_2(a, (a - 3\nu)/4, (a - 3\nu)/4) = (3a - \nu)/4$.*

Having located the trailing edge, we now solve equations (32) in the neighborhood of the trailing edge. We first consider equation (38). We use (30) to differentiate M/s^2 at the trailing edge $u_1 = a$, $u_2 = u_3 = (a - 3\nu)/4$, to find

$$\frac{\partial}{\partial u_2} \left[\frac{M}{s^2} \right] = \frac{\partial}{\partial u_3} \left[\frac{M}{s^2} \right] = \frac{\pi}{8(a + \nu)} ,$$

which shows that equation (38) or equivalently (37) can be inverted to give u_3 as a decreasing function of u_2

$$u_3 = A(u_2) \quad (39)$$

in a neighborhood of $u_2 = u_3 = (a - 3\nu)/4$.

We now extend the solution (39) of equation (37) in the region $a > u_2 > (a - 3\nu)/4 > u_3 > b$ as far as possible. We deduce from Lemma 4 that

$$\frac{\partial \lambda_2}{\partial u_2} > 0 , \quad \frac{\partial \lambda_3}{\partial u_3} < 0 \quad (40)$$

on the solution of (37). Because of (36) and (40), solution (39) of equation (37) can be extended as long as $a > u_2 > (a - 3\nu)/4 > u_3 > 0$.

There are two possibilities: (i) u_2 touches a before or simultaneously as u_3 reaches b and (ii) u_3 touches b before u_2 reaches a .

It follows from (23) that

$$\lambda_2(a, a, u_3) > \lambda_3(a, a, u_3) \quad \text{for } b \leq u_3 < a .$$

This shows that (i) is impossible. Hence, u_3 will touch b before u_2 reaches a . When this happens, equation (37) becomes

$$\lambda_2(a, u_2, b) - \lambda_3(a, u_2, b) = 0 . \quad (41)$$

Lemma 8 *Equation (41) has a simple zero in the region $b < u_2 < a$, counting multiplicities. Denoting the zero by u^* , then $\lambda_2(a, u_2, b) - \lambda_3(a, u_2, b)$ is positive for $u_2 > u^*$ and negative for $u_2 < u^*$.*

Proof. We use (26) and (29) to prove the lemma. In equation (26), $K - E$ and $E - (1 - s)K$ are all positive for $0 < s < 1$ in view of (A.9). We claim that

$$M(a, u_2, b) = 0 \quad \text{for } u_2 = b , \quad M(a, u_2, b) < 0 \quad \text{for } u_2 \text{ near } b ,$$

and

$$M(a, u_2, b) > 0 \quad \text{for } u_2 = a .$$

The equality and the first inequality follow from expansion (30) and $a + \nu > 4(b + \nu)$. The second inequality is obtained by applying (A.7) and (A.8) to (27).

We conclude from the two inequalities that $M(a, u_2, b)$ has a zero in $b < u_2 < a$. This zero is unique because $M(a, u_2, b)$, in view of (29), is a convex function of u_2 . This zero is exactly u^* and the rest of the theorem is proven easily. $\square$

Having solved equation (37) for u_3 as a decreasing function of u_2 for $(a - 3\nu)/4 \leq u_2 \leq u^*$, we turn to equations (32). Because of (36) and (40), the second equation of (32) gives u_2 as an increasing function of x/t , for $(3a - \nu)/4 \leq x/t \leq \alpha$, where

$$\alpha = \lambda_2(a, u^*, b).$$

Consequently, u_3 is a decreasing function of x/t in the same interval.

Lemma 9 *The last two equations of (32) can be inverted to give u_2 and u_3 as increasing and decreasing functions, respectively, of the self-similarity variable x/t in the interval $(3a - \nu) \leq x/t \leq \alpha$, where $\alpha = \lambda_2(a, u^*, b)$ and u^* is given in Lemma 8.*

We now turn to equations (33). We want to solve the second equation when $x/t > \alpha$ or equivalently when $u_2 > u^*$. According to Lemma 8, $\lambda_2(a, u_2, b) - \lambda_3(a, u_2, b) > 0$ for $u^* < u_2 < a$, which, by Lemma 4, shows that

$$\frac{\partial \lambda_2(a, u_2, b)}{\partial u_2} > 0 .$$

Hence, the second equation of (33) can be solved for u_2 as an increasing function of x/t as long as $u^* < u_2 < a$. When u_2 reaches a , we have

$$x/t = \lambda_2(a, a, b) = 2a + b + 2\nu ,$$

where we have used (23) in the last equality. We have therefore proved the following result.

Lemma 10 *The second equation of (33) can be inverted to give u_2 as an increasing function of x/t in the interval $\alpha \leq x/t \leq 2a + b + 2\nu$.*

We are ready to conclude the proof of Theorem 5.

The Burgers solutions (34) and (35) are trivial.

According to Lemma 9, the last two equations of (32) determine u_2 and u_3 as functions of x/t in the region $(3a - \nu)/4 \leq x/t \leq \alpha$. By the first part of Lemma 6, the resulting u_1 , u_2 and u_3 satisfy the Whitham equations (3). Furthermore, the boundary condition (9) is satisfied at the trailing edge $x/t = (3a - \nu)/4$.

Similarly, by Lemma 10, the second equation of (33) determines u_2 as a function of x/t in the region $\alpha \leq x/t \leq 2a + b + 2\nu$. It then follows from the second part of Lemma 6 that u_1 , u_2 and u_3 of (33) satisfy the Whitham equations (3). They also satisfy the boundary condition (10) at the leading edge $x = (2a + b + 2\nu)t$.

We have therefore completed the proof of Theorem 5.

A graph of the Whitham solution for the initial data (31) of type I is given in Figure 2. It is obtained by plotting the exact solutions of (32) and (33).

4.2 Type II: $a + \nu \leq 4(b + \nu)$

Theorem 11 *(see Figure 3.) For the step-like initial data (31) with $0 < (a + \nu)/4 \leq b + \nu < a + \nu$, the solution of the Whitham equations (3) is given by*

$$u_1 = a , \quad x = \lambda_2(a, u_2, b) t , \quad u_3 = b \tag{42}$$

for $\lambda_2(a, b, b) < x/t < \lambda_2(a, a, b)$, where $\lambda_2(a, b, b) = a + 2b + 2\nu - 4(a - b)(b + \nu)/(a + \nu)$ and $\lambda_2(a, a, b) = 2a + b + 2\nu$. Outside this interval, the solution of (2) is given by

$$u \equiv a \quad x/t \leq \lambda_2(a, b, b)$$

and

$$u \equiv b \quad x/t \geq \lambda_2(a, a, b) .$$

Fig. 3. Self-Similar solution of the Whitham equations for $a = 2$, $b = 0.8$ and $\nu = 1/20$ of type II.

Proof.

We will give a brief proof, since the arguments are, more or less, similar to those in the proof of Theorem 5.

It suffices to show that $\lambda_2(a, u_2, b)$ is an increasing function of u_2 for $b < u_2 < a$. Using the inequality (A.9) to estimate the right hand side of (28), we obtain

$$\frac{dM(a, u_2, b)}{du_2} > \frac{(a + \nu)(u_2 - b)E(s)}{2(2 - s)(a - b)^2(u_2 + \nu)^2} \{2(u_2 + \nu) + 2(b + \nu) - (a + \nu)\} > 0$$

for $b < u_2 < a$, where we have used $(a + \nu)/4 \leq b + \nu$ in the second inequality. Since $M(a, u_2, b) = 0$ at $u_2 = b$ in view of (30), this implies that $M(a, u_2, b) > 0$ for $b < u_2 < a$. It then follows from (26) that $\lambda_2(a, u_2, b) - \lambda_3(a, u_2, b) > 0$. By Lemma 4, we conclude that

$$\frac{d\lambda_2(a, u_2, b)}{du_2} > 0$$

for $b < u_2 < a$.

□

A graph of the Whitham solution for initial data (31) of type II is given in Figure 3. It is obtained by plotting the exact solution of (42).

5 Smooth Initial Data

In this section, we will study the initial value problem of the Whitham equations when the initial values are given by a smooth monotone function $u_0(x)$. Since the Burgers solution of (2) will never develop a shock when $u_0(x)$ is an increasing function, we will be interested only in the case that $u_0(x)$ is a decreasing function.

We consider the initial function $u_0(x)$ which is a decreasing function and is bounded at $x = \pm\infty$

$$\lim_{x \rightarrow -\infty} u_0(x) = a, \quad \lim_{x \rightarrow +\infty} u_0(x) = b. \quad (43)$$

By Theorem 1 and Lemma 3, we can use the hodograph transform,

$$x = \lambda_i(u_1, u_2, u_3)t + w_i(u_1, u_2, u_3), \quad i = 1, 2, 3, \quad (44)$$

to solve the Whitham equations (3). Here, w_i 's satisfy a linear over-determined system of type (13)

$$\frac{\partial w_i}{\partial u_j} = B_{ij}(w_i - w_j), \quad (45)$$

where B_{ij} 's are given in Lemma 3.

The boundary conditions on w_i 's are obtained by observing that the hodograph solution (44) of the Whitham equations (3) must match the characteristic solution (11) of the Burgers equation (2) at the trailing and leading edges in the fashion of (9-10). By (22-23), w_i 's must satisfy the boundary conditions,

$$\begin{cases} w_1(u_1, u_1, u_3) = w_2(u_1, u_1, u_3), \\ w_3(u_1, u_1, u_3) = f(u_3), \end{cases} \quad (46)$$

$$\begin{cases} w_1(u_1, u_3, u_3) = f(u_1), \\ w_2(u_1, u_3, u_3) = w_3(u_1, u_3, u_3), \end{cases} \quad (47)$$

where $f(u)$ is the inverse of the initial function $u_0(x)$.

Analogous to the KdV case [14,15], equations (45) subject to boundary conditions (46-47) are related to a boundary value problem of a linear over-determined system of Euler-Poisson-Darboux type (cf. (5))

$$2(u_i - u_j) \frac{\partial^2 q}{\partial u_i \partial u_j} = \frac{\partial q}{\partial u_i} - \frac{\partial q}{\partial u_j}, \quad i, j = 1, 2, 3, \quad (48)$$

$$q(u, u, u) = f(u), \quad (49)$$

for $i, j = 1, 2, 3$. The solution is unique and symmetric in u_1, u_2, u_3 . It is given explicitly by [14]

$$q(u_1, u_2, u_3) = \frac{1}{2\sqrt{2}\pi} \int_{-1}^1 \int_{-1}^1 \frac{f\left(\frac{1+u}{2} \frac{1+v}{2} u_1 + \frac{1+u}{2} \frac{1-v}{2} u_2 + \frac{1-u}{2} u_3\right)}{\sqrt{(1-u)(1-v^2)}} du dv. \quad (50)$$

Theorem 12 *If $q(u_1, u_2, u_3)$ is a solution of (48) and (49), then $w_i(u_1, u_2, u_3)$'s given by*

$$w_i = [\lambda_i(u_1, u_2, u_3) - \gamma] \frac{\partial q(u_1, u_2, u_3)}{\partial u_i} + q(u_1, u_2, u_3), \quad (51)$$

where $\gamma = u_1 + u_2 + u_3 + 2\nu$, solve equations (45) and satisfy boundary conditions (46-47).

Proof.

By Lemma 3 and (48), we obtain

$$[\lambda_j - \gamma] \left[\frac{\partial q}{\partial u_i} - \frac{\partial q}{\partial u_j} \right] B_{ij} = \left(\frac{\partial q}{\partial u_j} - \frac{\partial q}{\partial u_i} \right) + [\lambda_i - \gamma] \frac{\partial^2 q}{\partial u_i \partial u_j}. \quad (52)$$

Using (51), we calculate

$$\begin{aligned} \frac{\partial w_i}{\partial u_j} &= \frac{\partial \lambda_i}{\partial u_j} \frac{\partial q}{\partial u_i} + [\lambda_i - \gamma] \frac{\partial^2 q}{\partial u_i \partial u_j} + \frac{\partial q}{\partial u_j} - \frac{\partial q}{\partial u_i}, \\ w_i - w_j &= [\lambda_i - \gamma] \left[\frac{\partial q}{\partial u_i} - \frac{\partial q}{\partial u_j} \right] + [\lambda_i - \lambda_j] \frac{\partial q}{\partial u_i}. \end{aligned}$$

Substituting these into (52), we find that w_i 's satisfy (45).

Finally, we shall check the boundary conditions (46-47). We only consider the leading edge, and the trailing edge can be handled in the same way.

Since $q(u_1, u_2, u_3)$ is symmetric in u_1, u_2 and u_3 , the first condition of (46) follows from (51) and (23).

For the second condition, it follows from (23) and (51) again that

$$w_3(u_1, u_1, u_3) = 2(u_3 - u_1) \frac{\partial q}{\partial u_3} + q . \quad (53)$$

Differentiating this with respect to u_1 yields,

$$\frac{\partial w_3}{\partial u_1} = -2 \frac{\partial q}{\partial u_3} + 2(u_3 - u_1) \left[\frac{\partial^2 q}{\partial u_1 \partial u_3} + \frac{\partial^2 q}{\partial u_2 \partial u_3} \right] + \frac{\partial q}{\partial u_1} + \frac{\partial q}{\partial u_2} = 0 ,$$

where we have used (48) in the last equality. Since $w_3(u_1, u_1, u_3)$ is independent of u_1 , we replace u_1 by u_3 in (53) and use (49) to obtain the second condition of (46).

□

Theorem 12 has been reported in [1] in the case of $\nu = 0$.

In the rest of this section, we study the hodograph transform (44) with w_i 's given by (50) and (51). We shall show that the transform can be solved for u_1 , u_2 and u_3 as functions of (x, t) within a cusp in the x - t plane.

Since $t_b = -[3 \min(u'_0(x))]^{-1}$ is the breaking time of the Burgers solution of (2), the breaking is caused by an inflection point in the initial data. If x_0 is this inflection point, then (x_b, t_b) is the breaking point on the evolving curve where $x_b = x_0 + [3u_0(x_0) + 2\nu]t_b$, and t_b is the breaking time. Without loss of generality, we may assume $x_b = 0$, $t_b = 0$ and denote $u_0(0)$ by $\hat{u}$. The effect of these choices is that we are starting at the breaking time, and the evolving curve is about to turn over at the point $(0, \hat{u})$ in the x - u plane. It immediately follows that

$$f(\hat{u}) = f'(\hat{u}) = f''(\hat{u}) = 0 , \quad (54)$$

where $x = f(u)$ is the inverse function of the decreasing initial data $u = u_0(x)$. On the assumption that $x = f(u)$ has only one inflection point, it follows from the monotonicity of the function $f(u)$ that

$$f''(u) = \begin{cases} < 0 & u > \hat{u} \\ = 0 & u = \hat{u} \\ > 0 & u < \hat{u} \end{cases} . \quad (55)$$

Under a little bit stronger condition than (55), we will be able to show that hodograph transform (44) can be inverted to give u_1 , u_2 and u_3 as functions of (x, t) in some domain of the x - t plane.

Theorem 13 *Suppose $u_0(x)$ is a decreasing function satisfying (43) with $a + \nu > b + \nu > 0$. If, in addition to (54), the inverse function $f(u)$ satisfies $f'''(u)$*

< 0 for $b < u < a$, then transform (44) with w_i 's given by (50) and (51) can be solved for u_1 , u_2 and u_3 as functions of (x, t) within a cusp in the x - t plane for all $t > 0$. Furthermore, these u_1 , u_2 and u_3 satisfy boundary conditions (46-47) on the boundary of the cusp.

The proof is based on a series of lemmas. The organization is as follows: we eliminate x from transform (44) to obtain two equations involving u_1 , u_2 , u_3 , and t . These two equations can be shown, for each fixed time after the breaking, to determine u_1 and u_3 as decreasing functions of u_2 within an interval whose end points depend on t . Substituting u_1 and u_3 as functions of u_2 into the hodograph transform, we find that, within a cusp in the x - t plane, u_2 is a function of (x, t) , and so, therefore, are u_1 and u_3 .

First, we conclude from formula (50)

Lemma 14 *If $f(u)$ satisfies the conditions of Theorem 13, then $q(u_1, u_2, u_3)$ given by (50) satisfies*

$$\frac{\partial^3 q}{\partial u_i \partial u_j \partial u_k} < 0, \quad i, j, k = 1, 2, 3.$$

Eliminating x from (44) yields

$$(\lambda_1 t + w_1) - (\lambda_2 t + w_2) = 0, \quad (56)$$

$$(\lambda_2 t + w_2) - (\lambda_3 t + w_3) = 0. \quad (57)$$

Using (51) for w_1 and w_2 , and (18) for λ_1 and λ_2 , we write

$$\begin{aligned} (\lambda_1 t + w_1) - (\lambda_2 t + w_2) &= (\lambda_1 - \gamma) \left[t + \frac{\partial q}{\partial u_1} \right] - (\lambda_2 - \gamma) \left[t + \frac{\partial q}{\partial u_2} \right] \\ &= \frac{2(u_1 - u_2)(u_3 + \nu)\Pi}{(u_2 + \nu)E} F(u_1, u_2, u_3), \end{aligned}$$

where

$$F = \left(t + \frac{\partial q}{\partial u_1} \right) + \frac{sE}{E - (1-s)K} \frac{u_2 + \nu}{u_1 + \nu} \left[t + \frac{\partial q}{\partial u_2} \right]. \quad (58)$$

Similarly, we use (51) for w_2 and w_3 to write

$$\begin{aligned} (\lambda_2 t + w_2) - (\lambda_3 t + w_3) &= (\lambda_2 - \lambda_3) \left(t + \frac{\partial q}{\partial u_2} \right) + (\lambda_3 - \gamma) \left(\frac{\partial q}{\partial u_2} - \frac{\partial q}{\partial u_3} \right) \\ &= \frac{2(u_2 - u_3)(u_3 + \nu)\Pi}{(u_2 + \nu)[K - E][E - (1-s)K]} G(u_1, u_2, u_3), \end{aligned}$$

where

$$G = M(u_1, u_2, u_3)(t + \frac{\partial q}{\partial u_2}) - 2(u_2 - u_3)[E - (1 - s)K] \frac{\partial^2 q}{\partial u_2 \partial u_3} . \quad (59)$$

In the derivation, we have used formula (26) for $\lambda_2 - \lambda_3$, formula (18) for λ_3 and equation (48).

Since (A.9) implies that $K(s) - E(s) > 0$ and $E(s) - (1 - s)K(s) > 0$, equations (56) and (57) are equivalent to

$$F(u_1, u_2, u_3) = 0 , \quad G(u_1, u_2, u_3) = 0 \quad (60)$$

for $0 < s < 1$.

5.1 The trailing edge

We first study the trailing edge. We use (A.5), (A.6), and (30) to expand

$$\begin{aligned} F = & t + \frac{\partial q}{\partial u_1} + \frac{2(u_2 + \nu)}{(u_1 + \nu)} (t + \frac{\partial q}{\partial u_2}) - \frac{3(u_2 + \nu)}{4(u_1 + \nu)} (t + \frac{\partial q}{\partial u_2}) s \\ & - \frac{3(u_2 + \nu)}{32(u_1 + \nu)} (t + \frac{\partial q}{\partial u_2}) s^2 + O(s^3) , \end{aligned} \quad (61)$$

and

$$\begin{aligned} G = & \frac{\pi}{2} \left\{ \left[\frac{u_2 + \nu}{2(u_1 + \nu)} + \frac{1}{16} \left(1 - \frac{3(u_1 - u_2)}{u_1 - u_3} \right) \right] (t + \frac{\partial q}{\partial u_2}) - \right. \\ & \left. - \frac{(u_1 - u_3)(u_2 + \nu)}{u_1 + \nu} \frac{\partial^2 q}{\partial u_2 \partial u_3} \right\} s^2 \\ & + \frac{\pi}{2} \left\{ \frac{3}{128} \left(1 - 5 \frac{u_1 - u_2}{u_1 - u_3} \right) (t + \frac{\partial q}{\partial u_2}) - \right. \\ & \left. - \frac{(u_1 - u_3)(u_2 + \nu)}{8(u_1 + \nu)} \frac{\partial^2 q}{\partial u_2 \partial u_3} \right\} s^3 + O(s^4) . \end{aligned} \quad (62)$$

Taking the limits of $F = 0$ and $G/s^2 = 0$ as $s \rightarrow 0$ and simplifying the results a bit, we obtain the equations governing the trailing edge

$$U(u_1, u_3) := (u_1 + \nu)(t + \frac{\partial q(u_1, u_3, u_3)}{\partial u_1}) + 2(u_3 + \nu)(t + \frac{\partial q(u_1, u_3, u_3)}{\partial u_2}) = 0 , \quad (63)$$

and

$$V(u_1, u_3) := [(u_3 + \nu) - \frac{1}{4}(u_1 + \nu)](t + \frac{\partial q}{\partial u_2}) - 2(u_1 - u_3)(u_3 + \nu) \frac{\partial^2 q}{\partial u_2 \partial u_3} = 0. \quad (64)$$

Solving for t from (63) and substituting it into (64), we use (48) to simplify the result and get

$$\begin{aligned} W(u_1, u_3) := & [(u_3 + \nu) - \frac{1}{4}(u_1 + \nu)](u_1 + \nu) \frac{\partial^2 q}{\partial u_1 \partial u_3} \\ & + [(u_1 + \nu) + 2(u_3 + \nu)](u_3 + \nu) \frac{\partial^2 q}{\partial u_2 \partial u_3} = 0. \end{aligned} \quad (65)$$

Obviously, equations (63) and (64) are equivalent to equations (63) and (65).

We now solve equation (65) for u_3 as a function of u_1 in the neighborhood of $u_1 = u_3 = \hat{u}$. We use formula (50) and the symmetry of q to write

$$\frac{\partial^2 q(u_1, u_3, u_3)}{\partial u_1 \partial u_3} = \frac{1}{16\sqrt{2\pi}} \int_{-1}^1 f''\left(\frac{1+\mu}{2}u_3 + \frac{1-\mu}{2}u_1\right) \frac{(1-\mu^2)}{\sqrt{1-\mu}} d\mu, \quad (66)$$

$$\frac{\partial^2 q(u_1, u_3, u_3)}{\partial u_2 \partial u_3} = \frac{1}{64\sqrt{2\pi}} \int_{-1}^1 f''\left(\frac{1+\mu}{2}u_3 + \frac{1-\mu}{2}u_1\right) \frac{(1+\mu)^2}{\sqrt{1-\mu}} d\mu. \quad (67)$$

For $u_1 = \hat{u}$, it follows from (55), (66) and (67) that equation (65) has only the solution $u_3 = \hat{u}$ in the neighborhood of $u_1 = u_3 = \hat{u}$.

For u_1 which is a little bigger than $\hat{u}$, we will show that there is a unique u_3 such that equation (65) holds. By (55), (66) and (67), we have

$$W(\hat{u}, \tilde{u}_3) > 0 \quad \text{for some } \tilde{u}_3 < \hat{u}.$$

Hence,

$$W(u_1, \tilde{u}_3) > 0 \quad \text{for } u_1 \text{ a bit larger than } \hat{u}.$$

For each of such u_1 's, we deduct from (55) and (65) again that

$$W(u_1, \hat{u}) < 0.$$

By the mean value theorem, we show that, for each u_1 that is slightly larger than $\hat{u}$, there exists a $u_3 < \hat{u}$ such that (65) holds. It is easy to check the uniqueness of u_3 .

Therefore, (65) determines u_3 as a function of u_1 , $u_3 = A(u_1)$, for small non-positive u_1 with $A(\hat{u}) = \hat{u}$. The smoothness of the function $f(u)$ and Lemma 14 imply that $A(u_1)$ is a smooth decreasing function of u_1 .

Next, substituting $u_3 = A(u_1)$ into (63), it is not hard to show that (63) determines u_1 as a function of t . We have therefore proved the short time version of the following lemma.

Lemma 15 *Under the conditions of Theorem 13, equations (63) and (64) have a unique solution $(u_1^-(t), u_2^-(t), u_3^-(t))$ with $u_2^-(t) = u_3^-(t)$ for all $t \geq 0$. The solution has the property that $u_1^-(t) > u_2^-(t) = u_3^-(t)$ for $t > 0$ and that $u_1^-(0) = u_2^-(0) = u_3^-(0) = \hat{u}$.*

Proof. We will now extend the solution $(u_1^-(t), u_2^-(t), u_3^-(t))$ of equations (63) and (64) for all $t > 0$. Before doing this, we need a lemma.

Lemma 16 *Under conditions of Theorem 13, the following hold:*

$$\frac{\partial^2 q}{\partial u_1 \partial u_2} = \frac{\partial^2 q}{\partial u_1 \partial u_3} < 0, \quad \frac{\partial^2 q}{\partial u_1^2} < 0, \quad t + \frac{\partial q}{\partial u_1} < 0,$$

and

$$t + \frac{\partial q}{\partial u_2} = t + \frac{\partial q}{\partial u_3} > 0,$$

at the solution (u_1, u_3, u_3) of (65) where $u_1 > u_3$.

Proof. By (48) and Lemma 14,

$$\frac{\partial^2 q}{\partial u_1 \partial u_3} - \frac{\partial^2 q}{\partial u_2 \partial u_3} = \frac{\partial}{\partial u_3} \left[\frac{\partial q}{\partial u_1} - \frac{\partial q}{\partial u_2} \right] = 2(u_1 - u_2) \frac{\partial^3 q}{\partial u_1 \partial u_2 \partial u_3} < 0, \quad (68)$$

which when combined with (65) gives

$$\frac{\partial^2 q}{\partial u_1 \partial u_3} < 0$$

as long as $4(u_3 + \nu) - (u_1 + \nu) > 0$. This inequality holds even when $4(u_3 + \nu) - (u_1 + \nu) \leq 0$. To see this, suppose the inequality fails at some point, at which $\partial_{u_2 u_3}^2 q$ must vanish because of (65). This would violate (68).

The other inequalities of Lemma 16 are shown in the same way.

□

We now calculate the partial derivatives of U and V at the solution (u_1, u_3, u_3) of (63) and (64),

$$\begin{aligned}
\frac{\partial U}{\partial u_1} &= t + \frac{\partial q}{\partial u_1} + (u_1 + \nu) \frac{\partial^2 q}{\partial u_1^2} + 2(u_3 + \nu) \frac{\partial^2 q}{\partial u_1 \partial u_3} < 0, \\
\frac{\partial U}{\partial u_3} &= 2\left(t + \frac{\partial q}{\partial u_3}\right) + 2(u_1 + \nu) \frac{\partial^2 q}{\partial u_1 \partial u_3} + 8(u_3 + \nu) \frac{\partial^2 q}{\partial u_2 \partial u_3} \\
&= \frac{1}{u_1 - u_3} \left[(u_1 + \nu) \left(t + \frac{\partial q}{\partial u_1}\right) + 2(u_3 + \nu) \left(t + \frac{\partial q}{\partial u_3}\right) \right] = 0, \\
\frac{\partial V}{\partial u_3} &= t + \frac{\partial q}{\partial u_2} + [(8(u_3 + \nu) - 3(u_1 + \nu))] \frac{\partial^2 q}{\partial u_2 \partial u_3} \\
&\quad - 2(u_1 - u_3)(u_3 + \nu) \left(\frac{\partial^3 q}{\partial u_2^2 \partial u_3} + \frac{\partial^3 q}{\partial u_2 \partial u_3^2} \right) \\
&= \frac{3(u_1 + \nu)^2 - 12(u_1 + \nu)(u_3 + \nu) + 24(u_3 + \nu)^2}{8(u_1 - u_3)(u_3 + \nu)} \left(t + \frac{\partial q}{\partial u_2}\right) \\
&\quad - 2(u_1 - u_3)(u_3 + \nu) \left(\frac{\partial^3 q}{\partial u_2^2 \partial u_3} + \frac{\partial^3 q}{\partial u_2 \partial u_3^2} \right) > 0,
\end{aligned}$$

where we have used Lemmas 14 and 16 to determine the signs of the derivatives. These show that the Jacobian

$$\frac{\partial(U, V)}{\partial(u_1, u_3)} \neq 0$$

on the solution (u_1, u_3, u_3) of equations (63) and (64) where $u_1 > u_3$.

Therefore, by the Implicit Function Theorem, equations (63) and (64) can be solved for $u_1^-(t)$, $u_2^-(t) = u_3^-(t)$ for all $t \geq 0$. Furthermore, it is easy to check that $u_1^-(t)$ is an increasing function of t . $\square$

5.2 The leading edge

At the leading edge, $u_1 = u_2$, i.e., $s = 1$, it follows from (A.7), (A.8), (58), and (59) that equations (60) turn out to be

$$t + \frac{\partial q}{\partial u_1}(u_1, u_1, u_3) = 0, \quad t + \frac{\partial q}{\partial u_3}(u_1, u_1, u_3) = 0.$$

In the same way as we handle Lemma 15, we can solve the above equations for u_1 and u_3 as functions of t , leading to the lemma.

Lemma 17 *Under the conditions of Theorem 13, system (60) has a unique solution $(u_1^+(t), u_2^+(t), u_3^+(t))$ with $u_1^+(t) = u_2^+(t)$ for all $t \geq 0$. The solution has the property that $u_1^+(t) = u_2^+(t) > u_3^+(t)$ for $t > 0$ and that $u_1^+(0) = u_2^+(0) = u_3^+(0) = \hat{u}$.*

5.3 Near the trailing edge

By Lemma 15, $(u_1^-(t), u_2^-(t), u_3^-(t))$ satisfies equations (63) and (64). For each fixed $t > 0$, we need to solve equations (60) for u_1 and u_3 as functions of u_2 in the neighborhood of $u_2^-(t)$. This is carried out in

Lemma 18 *For each $t > 0$, equations (60) can be solved for u_1 and u_3 in terms of u_2 in the neighborhood of $(u_1^-(t), u_2^-(t), u_3^-(t))$*

$$\begin{cases} u_1 = M(u_2) \\ u_3 = N(u_2) \end{cases} \quad (69)$$

such that $u_1^-(t) = M(u_2^-(t))$ and $u_3^-(t) = N(u_2^-(t))$, Moreover, for $u_2 > u_2^-(t)$,

$$N(u_2) < u_2 < M(u_2). \quad (70)$$

Proof. Calculating the first partial derivatives of F and G/s^2 of (61) and (62) at $(u_1^-(t), u_2^-(t), u_3^-(t))$, where $u_2^-(t) = u_3^-(t)$, and using (48), we find

$$\begin{aligned} \frac{\partial F}{\partial u_1} &= \frac{\partial^2 q}{\partial u_1^2} - \frac{2(u_2 + \nu)}{(u_1 + \nu)^2} \left(t + \frac{\partial q}{\partial u_2} \right) + \frac{2(u_2 + \nu)}{u_1 + \nu} \frac{\partial^2 q}{\partial u_1 \partial u_2} < 0, \\ \frac{\partial F}{\partial u_2} &= \frac{\partial^2 q}{\partial u_1 \partial u_2} + \left[\frac{2}{u_1 + \nu} - \frac{3}{4} \frac{1}{u_1 - u_3} \right] \left(t + \frac{\partial q}{\partial u_2} \right) + \\ &\quad + \frac{6(u_2 + \nu)}{u_1 + \nu} \frac{\partial^2 q}{\partial u_2 \partial u_3} = 0, \\ \frac{\partial F}{\partial u_3} &= \frac{\partial^2 q}{\partial u_1 \partial u_3} + \frac{3}{4} \frac{1}{u_1 - u_3} \left(t + \frac{\partial q}{\partial u_2} \right) + \frac{2(u_2 + \nu)}{u_1 + \nu} \frac{\partial^2 q}{\partial u_2 \partial u_3} = 0, \\ \frac{\partial(G/s^2)}{\partial u_2} &= \frac{\pi}{2} \left\{ \frac{19(u_1 + \nu) - 16(u_3 + \nu)}{32(u_1 - u_3)(u_1 + \nu)} \left(t + \frac{\partial q}{\partial u_2} \right) - \frac{u_1 - u_2}{2(u_1 + \nu)} \frac{\partial^2 q}{\partial u_2 \partial u_3} \right\} \\ &= \frac{2(u_1 + \nu)^2 + 9(u_1 + \nu)(u_3 + \nu) - 8(u_3 + \nu)^2}{64(u_1 - u_3)(u_1 + \nu)(u_2 + \nu)} \pi \left(t + \frac{\partial q}{\partial u_2} \right) > 0, \\ \frac{\partial(G/s^2)}{\partial u_3} &= \frac{\pi}{2} \left\{ \left[-\frac{3}{16(u_1 - u_3)} + \frac{3(u_1 + \nu)}{32(u_1 - u_3)(u_2 + \nu)} \right] \left(t + \frac{\partial q}{\partial u_2} \right) + \right. \\ &\quad \left. + \frac{3(u_2 + \nu)}{2(u_1 + \nu)} \frac{\partial^2 q}{\partial u_2 \partial u_3} - \frac{(u_1 - u_3)(u_2 + \nu)}{u_1 + \nu} \frac{\partial^3 q}{\partial u_2 \partial u_3^2} \right\} \\ &= \frac{\pi}{2} \left\{ \frac{3[(u_1 + \nu)^2 - 4(u_1 + \nu)(u_3 + \nu) + 8(u_3 + \nu)^2]}{32(u_1 - u_3)(u_1 + \nu)(u_2 + \nu)} \left(t + \frac{\partial q}{\partial u_2} \right) \right. \\ &\quad \left. - \frac{(u_1 - u_3)(u_2 + \nu)}{u_1 + \nu} \frac{\partial^3 q}{\partial u_2 \partial u_3^2} \right\} > 0, \end{aligned}$$

where we have used (63) and (64) to simplify the results, and Lemmas 14 and 16 to determine the signs of the derivatives.

These prove the non-vanishing of the Jacobian

$$\frac{\partial(F, G/s^2)}{\partial(u_1, u_3)}$$

at $(u_1^-(t), u_2^-(t), u_3^-(t))$. Hence, equations (60) can be solved for

$$\begin{cases} u_1 = M(u_2) \\ u_3 = N(u_2) \end{cases}$$

in a neighborhood of $u_2^-(t)$ such that $u_1^-(t) = M(u_2^-(t))$ and $u_3^-(t) = N(u_2^-(t))$. Furthermore, $N(u_2)$ is a decreasing function of u_2 and so (70) holds. $\square$

5.4 The passage from the trailing edge to the leading edge

We shall show that, for each fixed $t > 0$, solutions (69) of equations (60) can be further extended as long as $N(u_2) < u_2 < M(u_2)$. The Jacobian of system (56) and (57) with respect to (u_1, u_3) has to be estimated along the extension.

Lemma 19 *Under the conditions of Theorem 13, the following inequalities hold for each $t > 0$.*

$$\frac{\partial(\lambda_1 t + w_1)}{\partial u_1} < 0, \quad \frac{\partial(\lambda_2 t + w_2)}{\partial u_2} > 0, \quad \frac{\partial(\lambda_3 t + w_3)}{\partial u_3} < 0 \quad (71)$$

on the solution (u_1, u_2, u_3) of (56) and (57) (or equivalently (60)) in the region $0 < u_3 + \nu < u_2 + \nu < u_1 + \nu$.

Proof. Using formulae (51) for w_1, w_2 , and w_3 , we see that (56) and (57) are equivalent to

$$[\lambda_1 - (u_1 + u_2 + u_3 + 2\nu)](t + \frac{\partial q}{\partial u_1}) = [\lambda_2 - (u_1 + u_2 + u_3 + 2\nu)](t + \frac{\partial q}{\partial u_2}), \quad (72)$$

$$[\lambda_2 - 2(u_1 + u_2 + u_3 + 2\nu)](t + \frac{\partial q}{\partial u_2}) = [\lambda_3 - (u_1 + u_2 + u_3 + 2\nu)](t + \frac{\partial q}{\partial u_3}). \quad (73)$$

By Lemma 16,

$$\frac{\partial^2 q(u_1, u_2, u_3)}{\partial u_1 \partial u_2} < 0, \quad \frac{\partial^2 q(u_1, u_2, u_3)}{\partial u_1 \partial u_3} < 0 \quad (74)$$

at the trailing edge.

We claim that inequalities (74) hold on the solution (u_1, u_2, u_3) of (56) and (57) as long as $0 < u_3 + \nu < u_2 + \nu < u_1 + \nu$.

We justify the claim by contradiction. Suppose otherwise, for instance at some point $(\bar{u}_1, \bar{u}_2, \bar{u}_3)$ on the solution of (56) and (57), with $0 < \bar{u}_3 + \nu < \bar{u}_2 + \nu < \bar{u}_1 + \nu$,

$$\frac{\partial^2 q}{\partial u_1 \partial u_2} = 0 .$$

In view of (48), this gives

$$\frac{\partial q}{\partial u_1} = \frac{\partial q}{\partial u_2} \quad \text{at } (\bar{u}_1, \bar{u}_2, \bar{u}_3) ,$$

which together with (19), (20), and (72) imply

$$t + \frac{1}{2} \frac{\partial q}{\partial u_1} = t + \frac{1}{2} \frac{\partial q}{\partial u_2} = 0 . \quad (75)$$

By (20), (21), (73), and (75), we obtain

$$t + \frac{\partial q}{\partial u_3} = 0 ,$$

which together with (48) gives

$$\frac{\partial^2 q}{\partial u_1 \partial u_2} = \frac{\partial^2 q}{\partial u_1 \partial u_3} = 0 \quad (76)$$

at $(\bar{u}_1, \bar{u}_2, \bar{u}_3)$.

On the other hand, by (48) and Lemma 14,

$$\frac{\partial^2 q}{\partial u_1 \partial u_2} - \frac{\partial^2 q}{\partial u_1 \partial u_3} = 2(u_2 - u_3) \frac{\partial^3 q}{\partial u_1 \partial u_2 \partial u_3} < 0$$

at $(\bar{u}_1, \bar{u}_2, \bar{u}_3)$. This contradicts (76) and the claim has been justified.

By (48), we have

$$2(u_1 - u_3) \frac{\partial^2 q}{\partial u_1 \partial u_3} = \frac{\partial q}{\partial u_1} - \frac{\partial q}{\partial u_3} .$$

Differentiating this with respect to u_1 yields

$$\frac{\partial^2 q}{\partial u_1^2} = 3 \frac{\partial^2 q}{\partial u_1 \partial u_3} + 2(u_1 - u_3) \frac{\partial^3 q}{\partial u_1^2 \partial u_3} < 0 , \quad (77)$$

where we have used (74) and Lemma 14 in the last step.

It follows from (74) and (48) that

$$\frac{\partial q}{\partial u_1} < \frac{\partial q}{\partial u_2}, \quad \frac{\partial q}{\partial u_1} < \frac{\partial q}{\partial u_3},$$

which when combined with (19), (20), (21), (72) and (73) gives

$$t + \frac{1}{2} \frac{\partial q}{\partial u_1} < 0, \quad t + \frac{1}{2} \frac{\partial q}{\partial u_2} > 0, \quad t + \frac{1}{2} \frac{\partial q}{\partial u_3} > 0 \quad (78)$$

on the solution (u_1, u_2, u_3) of (56) and (57) in the region $0 < u_3 + \nu < u_2 + \nu < u_1 + \nu$.

Therefore, by (51),

$$\frac{\partial(\lambda_1 t + w_1)}{\partial u_1} = \frac{\partial \lambda_1}{\partial u_1} \left(t + \frac{\partial q}{\partial u_1} \right) + [\lambda_1 - (u_1 + u_2 + u_3 + 2\nu)] \frac{\partial^2 q}{\partial u_1^2} < 0,$$

where in the last inequality we have used (19), (77), (78), and

$$\frac{\partial \lambda_1}{\partial u_1} = \frac{I \partial_{u_i u_i}^2 I}{(\partial_{u_i} I)^2} > 0.$$

This proves the first inequality of (71).

Next we shall prove the rest of Lemma 19. By (48), we have

$$2(u_2 - u_3) \frac{\partial^2 q}{\partial u_2 \partial u_3} = \frac{\partial q}{\partial u_2} - \frac{\partial q}{\partial u_3}.$$

Differentiating this with respect to u_2 yields

$$\frac{\partial^2 q}{\partial u_2^2} = 3 \frac{\partial^2 q}{\partial u_2 \partial u_3} + 2(u_2 - u_3) \frac{\partial^3 q}{\partial u_2^2 \partial u_3}. \quad (79)$$

Using (48) to rewrite (73), we obtain

$$(\lambda_2 - \lambda_3) \left[t + \frac{\partial q}{\partial u_3} \right] + 2[\lambda_3 - (u_1 + u_2 + u_3 + 2\nu)] \frac{\partial^2 q}{\partial u_2 \partial u_3} (u_2 - u_3) = 0 \quad (80)$$

which together with (79) gives

$$\begin{aligned} & 3 \frac{\lambda_2 - \lambda_3}{u_2 - u_3} \left(t + \frac{\partial q}{\partial u_3} \right) + 2[\lambda_2 - (u_1 + u_2 + u_3 + 2\nu)] \frac{\partial^2 q}{\partial u_2^2} \\ & = 4[\lambda_2 - (u_1 + u_2 + u_3 + 2\nu)] (u_2 - u_3) \frac{\partial^3 q}{\partial u_2^2 \partial u_3} > 0, \end{aligned} \quad (81)$$

where we have used (21) and Lemma 14 in the last inequality.

It follows from (51) that

$$\begin{aligned}
\frac{\partial(\lambda_2 t + w_2)}{\partial u_2} &= \frac{\partial \lambda_2}{\partial u_2} \left(t + \frac{\partial q}{\partial u_2} \right) + [\lambda_2 - (u_1 + u_2 + u_3 + 2\nu)] \frac{\partial^2 q}{\partial u_2^2} \\
&> \frac{3}{2} \frac{\lambda_2 - \lambda_3}{u_2 - u_3} \left(t + \frac{\partial q}{\partial u_2} \right) + [\lambda_2 - (u_1 + u_2 + u_3 + 2\nu)] \frac{\partial^2 q}{\partial u_2^2} \\
&= \frac{3}{2} \frac{\lambda_2 - \lambda_3}{u_2 - u_3} \left(t + \frac{\partial q}{\partial u_3} \right) + [\lambda_2 - (u_1 + u_2 + u_3 + 2\nu)] \frac{\partial^2 q}{\partial u_2^2} \\
&\quad + 3(\lambda_2 - \lambda_3) \frac{\partial^2 q}{\partial u_2 \partial u_3} \\
&> 3(\lambda_2 - \lambda_3) \frac{\partial^2 q}{\partial u_2 \partial u_3} \geq 0,
\end{aligned}$$

where we have used Lemma 4, (78) in the first inequality, and (81) in the second one. The last inequality is due to the fact that $\lambda_2 - \lambda_3$ and $\partial_{u_2 u_3}^2 q$ have the same sign because of (80).

This proves the second inequality of (71). In the same way, we can prove the last one. $\square$

We are ready to conclude the proof of Theorem 13.

Proof of Theorem 13: By Lemma 18, equations (60) can be solved for

$$\begin{cases} u_1 = M(u_2) \\ u_3 = N(u_2) \end{cases}$$

in the neighborhood of $(u_1^-(t), u_2^-(t), u_3^-(t))$. Furthermore, (70) holds if $u_2 > u_2^-(t)$. We shall extend the solution in the positive u_2 direction as far as possible. It follows from Corollary 2 and Lemma 19 that, along the extension of (69) in the region $u_1 + \nu > u_2 + \nu > u_3 + \nu > 0$, the Jacobian matrix of (56) and (57) is diagonal and therefore is nonsingular. Furthermore, equations (56) and (57) determines (69) as two decreasing functions of u_2 .

This immediately guarantees that (69) can be extended as far as necessary in the region $u_1 + \nu > u_2 + \nu > u_3 + \nu > 0$. Since $M(u_2)$ is decreasing, (69) stops at some point $u_2^+(t)$ where, obviously, $M(u_2^+(t)) = u_2^+(t)$. Therefore, we have shown that (56) and (57) determine u_1 and u_3 as decreasing functions of u_2 over the interval $[u_2^-(t), u_2^+(t)]$.

Let

$$\begin{cases} u_1^+(t) = M(u_2^+(t)) \\ u_3^+(t) = N(u_2^+(t)) . \end{cases}$$

Clearly, $(u_1^+(t), u_2^+(t), u_3^+(t))$ solves system (60) at the leading edge $u_1 = u_2$. Hence, these $u_1^+(t)$, $u_2^+(t)$ and $u_3^+(t)$ are exactly the ones appearing in Lemma 17.

Substituting (69) into (44), we obtain

$$x = \lambda_2(M(u_2), u_2, N(u_2))t + w_2(M(u_2), u_2, N(u_2))$$

which by Corollary 2 and Lemma 19 clearly determines x as an increasing function of u_2 over interval $[u_2^-(t), u_2^+(t)]$. It follows that, for each fixed $t > 0$, u_2 is a function of x over the interval $[x^-(t), x^+(t)]$, and that therefore so are u_1 and u_3 , where

$$x^\pm(t) = \lambda_2(u_1^\pm(t), u_2^\pm(t), u_3^\pm(t))t + w_2(u_1^\pm(t), u_2^\pm(t), u_3^\pm(t)) . \quad (82)$$

Thus, (44) can be solved for

$$u_1 = u_1(x, t) , \quad u_2 = u_2(x, t) , \quad u_3 = u_3(x, t)$$

within a wedge

$$\begin{aligned} x^-(t) &< x < x^+(t) && \text{for } t > 0 , \\ x^-(0) &= x^+(0) = 0 , \end{aligned} \quad (83)$$

where we have used (82), Lemma 15, and Lemma 17 in the last equations.

Boundary conditions (9) and (10) can be checked easily. The proof of Theorem 13 would be completed if we can verify that the wedge is indeed a cusp. First we need a lemma.

Lemma 20 *At $(u_1^-(t), u_2^-(t), u_3^-(t))$,*

$$\frac{\partial(\lambda_2 t + w_2)}{\partial u_2} = \frac{\partial(\lambda_3 t + w_3)}{\partial u_3} = 0 , \quad (84)$$

while at $(u_1^+(t), u_2^+(t), u_3^+(t))$,

$$\frac{\partial(\lambda_1 t + w_1)}{\partial u_1} = \frac{\partial(\lambda_2 t + w_2)}{\partial u_2} = 0 . \quad (85)$$

Proof.

Using expansions (A.5) and (A.6), we obtain from (25) that

$$\frac{\partial \lambda_2}{\partial u_2} = \frac{6[(u_3 + \nu) - \frac{1}{4}(u_1 + \nu)]}{u_1 + \nu}$$

at $(u_1^-(t), u_2^-(t), u_3^-(t))$.

By (51), we have

$$\begin{aligned} \frac{\partial(\lambda_2 t + w_2)}{\partial u_2} &= \frac{6[(u_3 + \nu) - \frac{1}{4}(u_1 + \nu)]}{(u_1 + \nu)} \left(t + \frac{\partial q}{\partial u_2}\right) \\ &\quad - \frac{4(u_1 - u_3)(u_3 + \nu)}{u_1 + \nu} \frac{\partial^2 q}{\partial u_2^2} = 0, \end{aligned}$$

where we have used (22) in the first equality, and (64) and (79) in the last equality. The proof also applies to the other equation of (84).

To prove (85), we proceed as follows. By (18), (A.7), and (A.8), we find

$$\frac{\partial \lambda_2}{\partial u_1} = O(K(s)) \quad \text{as } s \rightarrow 1. \quad (86)$$

By Corollary 2 and formula (51), we calculate the derivative on the solution of (56) and (57)

$$\begin{aligned} 0 &= \frac{\partial(\lambda_2 t + w_2)}{\partial u_1} \\ &= \frac{\partial \lambda_2}{\partial u_1} \left(t + \frac{\partial q}{\partial u_2}\right) + \frac{1}{2}[\lambda_2 - (u_1 + u_2 + u_3 + 2\nu)] \frac{\partial^2 q}{\partial u_1 \partial u_2} + \frac{\partial q}{\partial u_1} - \frac{\partial q}{\partial u_2}, \end{aligned}$$

which when combined with (23) and (86) gives

$$\lim_{s \rightarrow 1} \left[t + \frac{\partial q}{\partial u_2}\right] K(s) = 0. \quad (87)$$

On the other hand, as in (86), we have

$$\frac{\partial \lambda_2}{\partial u_2} = O(K(s)) \quad \text{as } s \rightarrow 1. \quad (88)$$

Therefore, by (51) we see that at (u_1^+, u_2^+, u_3^+)

$$\frac{\partial(\lambda_2 t + w_2)}{\partial u_2} = \frac{\partial \lambda_2}{\partial u_2} \left(t + \frac{1}{2} \frac{\partial q}{\partial u_2}\right) + [\lambda_2 - (u_1 + u_2 + u_3 + 2\nu)] \frac{\partial^2 q}{\partial u_2^2} = 0,$$

where, by (87) and (88), the first term vanishes, while the second term vanishes because of (23). This proves the second equality of (85). In the same way, we can check the other equality of (85). $\square$

Now we continue to finish the proof of Theorem 13. Differentiating (82) with respect to t , by Corollary 2 and Lemma 20 we obtain

$$\begin{aligned}\frac{dx^\pm(t)}{dt} &= \frac{\partial(\lambda_2 t + w_2)}{\partial u_2} \frac{du_2^\pm}{dt} + \lambda_2(u_1^\pm, u_2^\pm, u_3^\pm) \\ &= \lambda_2(u_1^\pm, u_2^\pm, u_3^\pm),\end{aligned}$$

which when combined with (22), (23), Lemma 15, and Lemma 17 gives

$$\frac{dx^\pm(t)}{dt} = 3\hat{u} + 2\nu \quad \text{at } t = 0.$$

Therefore, wedge (83) is a cusp. This completes the proof of Theorem 13.

We immediately conclude from Theorem 1 and Theorem 13 the following result on the initial value problem of the Whitham equations.

Theorem 21 *For a decreasing initial function $u_0(x)$ whose inverse function $f(u)$ satisfying the conditions of Theorem 13, the Whitham equations (3) have a solution $(u_1(x, t), u_2(x, t), u_3(x, t))$ within a cusp for all positive time. The Burgers solution of (2) exists outside the cusp. The Whitham solution matches the Burgers solution on the boundary of the cusp in the fashion of (9) and (10).*

We close this paper with two observations. First, it is obvious from the proof of Theorem 21 that one should expect local (in time) results if local conditions are assumed. Namely, if the global condition $f'''(u) < 0$ for all $b < u < a$ in Theorem 21 is replaced by a local condition $f'''(u) < 0$ in the neighborhood of the breaking point $\hat{u}$, the results of Theorem 21 are only true for a short time after the breaking time.

Second, a hump-like initial function can be decomposed into a decreasing and an increasing parts. It is known that the decreasing part causes the Burgers solution of (2) to develop finite time singularities while the increasing part does not. These two pieces of data would not interact with each other for a short time after the breaking of the Burgers solution. As a consequence, a short time result also holds for a hump-like initial function.

A Complete Elliptic Integrals

In this Appendix, we list some of the well-known properties of the complete elliptic integrals of the first, second and third kind.

These are the derivative formulae

$$\frac{dK(s)}{ds} = \frac{E(s) - (1-s)K(s)}{2s(1-s)} , \quad (\text{A.1})$$

$$\frac{dE(s)}{ds} = \frac{E(s) - K(s)}{2s} , \quad (\text{A.2})$$

$$\frac{d\Pi(\rho, s)}{d\rho} = \frac{\rho E(s) + (s - \rho)K(s) + (\rho^2 - s)\Pi(\rho, s)}{2\rho(1 - \rho)(\rho - s)} , \quad (\text{A.3})$$

$$\frac{d\Pi(\rho, s)}{ds} = \frac{E(s) - (1-s)\Pi(\rho, s)}{2(1-s)(s - \rho)} . \quad (\text{A.4})$$

$K(s)$ and $E(s)$ have the expansions

$$K(s) = \frac{\pi}{2} \left[1 + \frac{s}{4} + \frac{9}{64}s^2 + \dots + \left(\frac{1 \cdot 3 \cdots (2n-1)}{2 \cdot 4 \cdots 2n} \right)^2 s^n + \dots \right] , \quad (\text{A.5})$$

$$E(s) = \frac{\pi}{2} \left[1 - \frac{s}{4} - \frac{3}{64}s^2 - \dots - \frac{1}{2n-1} \left(\frac{1 \cdot 3 \cdots (2n-1)}{2 \cdot 4 \cdots 2n} \right)^2 s^n - \dots \right] \quad (\text{A.6})$$

for $|s| < 1$. They also have the asymptotics

$$K(s) \approx \frac{1}{2} \log \frac{16}{1-s} , \quad (\text{A.7})$$

$$E(s) \approx 1 + \frac{1}{4}(1-s) \left[\log \frac{16}{1-s} - 1 \right] \quad (\text{A.8})$$

when s is close to 1. They satisfy the inequalities [14]

$$\frac{1}{1 - \frac{s}{2}} < \frac{K(s)}{E(s)} < \frac{1 - \frac{s}{2}}{1 - s} \quad \text{for } 0 < s < 1 . \quad (\text{A.9})$$

The complete elliptic integral of the third kind has the following behavior

$$\Pi(\rho, s) = \frac{\pi}{2} \quad \text{when } \rho = 0, s = 0 , \quad (\text{A.10})$$

$$\frac{\Pi(\rho, s)}{K(s)} \approx \frac{1}{1 - \rho} \quad \text{when } s \text{ is close to } 1 . \quad (\text{A.11})$$
